Abstract. Three complementary views on the QCD vacuum structure, all based on eigenmodes of the overlap operator, are reported in their interrelation: (i) spectral density, localization and chiral properties of the modes, (ii) the possibility of filtering the field strength with the aim to detect selfdual and antiselfdual domains and (iii) the various faces of the topological charge density, with and without a cutoff $\lambda_{\text{cut}} = O(\Lambda_{QCD})$. The techniques are tested on quenched $SU(3)$ configurations.

Keywords: lattice fermions, localization, topological charge

PACS: 11.15.-q, 11.15.Ha, 12.38.Aw

INTRODUCTION

Attempts to catch the structure of the QCD vacuum on the lattice were mostly inspired by the instanton/caloron picture, and appropriate lumps were searched for in the gluonic lattice topological charge density $q(x)$. With the advent of overlap fermions, the fermionic definition of the topological charge density has become viable, from the scale of the lattice spacing a up to the infrared. This is possible since the Ginsparg-Wilson approach provides lattice fermions with perfect chiral properties. Results concerning the vacuum structure, based on the eigenmodes of the overlap Dirac operator that have been collected in the QCDSF collaboration [1, 2], are described in this contribution.

PROPERTIES OF THE LOWEST EIGENMODES

We analyze a large set of overlap eigenmodes, $O(150)$ per lattice configuration, for five ensembles of quenched Yang-Mills theory generated with the Lüscher-Weisz action. This action is important to avoid dislocations. The analysis is performed on $12^3 \times 24$, $16^3 \times 32$ and $24^3 \times 48$ lattices at $\beta = 8.45$, on a $12^3 \times 24$ lattice at $\beta = 8.10$ and on a $16^3 \times 32$ lattice at $\beta = 8.00$. In Fig. 1 (left) the spectral densities for the three volumes at $\beta = 8.45$ are presented. The fit to quenched chiral perturbation theory [3] requires to know the distribution $w(Q)$ of topological charge, easily obtained from the number and chirality ± 1 of the zeromodes, $Q = N_- - N_+$, per configuration. Fig. 1 shows the fit of

the spectral densities according to

$$\rho(\lambda, V) = \Sigma_{\text{eff}}(V, \lambda) \sum_Q w(Q) \rho_Q(\lambda \sqrt{V} \Sigma_{\text{eff}}(V, \lambda)), \quad (1)$$

with the microscopic spectral density $\rho_Q(x) = (x/2)(J_{|Q|}^2(x) - J_{|Q|+1}(x)J_{|Q|-1}(x))$ in the fixed Q sector, leading to an estimate of the quark condensate, $\Sigma^{\overline{\text{MS}}}(2 \text{ GeV}) = (231(20) \text{ MeV})^3$.

In Fig. 1 (right) the average inverse participation ratio (IPR) of the zeromodes and non-zeromodes is presented. In the spectral region of strong volume dependence the modes are highly localized, the spread of the IPRs is large and the level compressibility $\alpha = \langle (N - \langle N \rangle)^2 \rangle / \langle N \rangle < 1$ (for N modes falling in some interval) is small. In the theory of the metal-insulator transition this situation is called “critical”, and the modes are multifractal. Fitting the V dependence of the IPRs, one can assign a dimension $d^*(p=2) \approx 2$ to the zeromodes and $d^*(p=2) \approx 3 - 3.5$ to the non-zeromodes below 100 MeV (see Fig. 2 (left), upper curve). Similar results of the MILC collaboration [4] have been obtained with Asqtad fermions. The IPRs of the higher modes are consistent with $d^*(2) \approx 4$. Generalized IPRs based on higher moments $I_\lambda^{(p)} = \sum_x p_\lambda(x)^p$ of the scalar density $p_\lambda(x) = \psi_\lambda^\dagger(x) \psi_\lambda(x)$ localize the peaks of $p_\lambda(x)$ in regions of lower dimension, $d^*(p > 2) < d^*(p=2)$. We find $d^*(p=10) < 1$ for zeromodes and $d^*(p=10) \sim 1$ for non-zeromodes with $\lambda < 100$ MeV. The multifractality evidenced in Fig. 2 (left) urges a more detailed study of the lowest eigenmodes, in particular closer to the continuum limit. Case studies [5] show that they might be pinned-down on low-dimension defects of the gauge field (monopoles and vortices, the candidates to create confinement).

Different from the high temperature phase [6], the distribution of local chirality of the lowest non-zeromodes peaks at non-zero values of the chirality variable

$$X_\lambda(x) = (4/\pi) \arctan \sqrt{p_{\lambda+}(x)/p_{\lambda-}(x)} - 1 \in [-1, +1]. \quad (2)$$

expressing the ratio between the density of the chirality components, $p_{\lambda\pm}(x) = \frac{1}{2} \psi_\lambda^\dagger(x) (1 \pm \gamma_5) \psi_\lambda(x)$. Focussing on the highest-ranking 1 % of lattice sites according

to the scalar density $p_\lambda(x)$, the histograms for the 10 lowest pairs $\pm\lambda$ are shown in Fig. 2 (right).

TOPOLOGICAL DENSITY AND A MEASURE OF SELF DUALITY

The *all-scale* topological charge density in terms of the overlap operator D_N is

$$q(x) = -\text{Tr}_{color,spinor} \left[\gamma_5 \left(1 - \frac{a}{2} D_N(x,x) \right) \right], \quad (3)$$

while the UV-filtered version $q_{\lambda_{\text{cut}}}(x)$ gets contributions to the trace only from modes with $|\lambda| < \lambda_{\text{cut}} \sim \Lambda_{QCD}$.

The density $q(x)$ satisfies the negativity of the topological correlator $C_q(r)$ [7] for $r \neq 0$ due to the diverging multiplicity of clusters at large enough β or $a \lesssim 0.1$ fm. At $\beta = 8.45$ one finds ≈ 75 such clusters per fm^4 that percolate at $|q(x)| = 0.25 q_{\text{max}}$. Clusters with different fractal dimensions $d^* < 3$ are visible at $|q(x)|$ above the percolation threshold. The global 3D structure discovered by Horvath *et al.* [8] appears below that level. The UV-filtered density with $\lambda_{\text{cut}} = 200$ MeV forms only one cluster per fm^4 percolating at $|q_{\lambda_{\text{cut}}}(x)| = 0.05 q_{\lambda_{\text{cut}}\text{max}}$.

Gattringer [9] proposed an UV filter for the field strength tensor using eigenmodes $\psi_\lambda(x)$ of the Dirac operator (T^a denotes a color generator in the fundamental representation)

$$F_{\mu\nu}^a(x) \propto \sum_j \lambda_j^2 f_{\mu\nu}^a(x|j), \text{ with } f_{\mu\nu}^a(x|j) = -(i/2) \psi_{\lambda_j}^\dagger(x) \gamma_\mu \gamma_\nu T^a \psi_{\lambda_j}(x). \quad (4)$$

This prescription yields a filtered field strength up to an (undetermined) normalization when only low-lying modes are included. With a filtered action density $\tilde{s}(x) = \text{Tr } F_{\mu\nu}(x) F_{\mu\nu}(x)$ and topological charge density $\tilde{q}(x) = \text{Tr } F_{\mu\nu}(x) \tilde{F}_{\mu\nu}(x)$, one gets an estimator for the local (anti-)selfduality analogous to Eq. (2),

$$R(x) = (4/\pi) \arctan \sqrt{(\tilde{s}(x) - \tilde{q}(x))/(\tilde{s}(x) + \tilde{q}(x))} - 1 \in [-1, +1]. \quad (5)$$

FIGURE 3. Comparison of the R -clusters for $R_{\text{cut}} = 0.99$ with the $q_{\lambda_{\text{cut}}}$ -clusters for $\lambda_{\text{cut}} = 100$ MeV (at 1/10 of the maximal density) for one timeslice of a $16^3 \times 32$ lattice configuration with $Q = 0$ generated at $\beta = 8.45$. The similarity is the same in all timeslices.

This observable has good cluster properties if a cut separates (anti-)selfdual domains from the rest of the lattice. For $R_{\text{cut}} \lesssim 1$ the number of such domains is practically stable under changing the cutoff. It depends, however, on the number of modes used in the filter. $R(x)$ is correlated with the local chirality $X_\lambda(x) \approx \pm 1$ of the low eigenmodes, and the R -cluster structure corresponds to the cluster structure of $q_{\lambda_{\text{cut}}}$, as demonstrated in Fig. 3, if both are tuned to the relevant number of modes ($\lambda_{\text{cut}} \sim \Lambda_{QCD}$).

CONCLUSION

The main conclusion is that overlap fermions can probe the lattice vacuum both in the ultraviolet and in the infrared. To see the phenomenologically known structure of 4D selfdual domains, some UV filtering by applying $\lambda_{\text{cut}} \sim \Lambda_{QCD}$ is necessary without the need of smoothing the gauge field. The *all-scale* topological charge density is multifractal, too, within the global 3D structure. It forms lower dimensional clusters above the percolation threshold. The phenomenological significance of the low-dimensional (singular) structures is still speculative.
